

BC COMS 2710: Computational Text Analysis

BARNARD COLLEGE OF COLUMBIA UNIVERSITY

Lecture 2 – Python Overview

Announcements

- Tutorial 1.1
 - Should be submitted today (Tuesday 05/04)
- Tutorial 1.2
 - Should be submitted tomorrow (Wednesday 05/05)
- Tutorial 1.3
 - Should be submitted Friday (05/07)
- Homework 01:
 - Due Monday 05/10
- Reading Week 1
 - Due Sunday 05/09

Updated Rubric

| Participation | 5% |
|---------------------|-----|
| 4 Homeworks | 30% |
| Reading reflections | 15% |
| Daily Tutorials | 20% |
| Final Project | 35% |

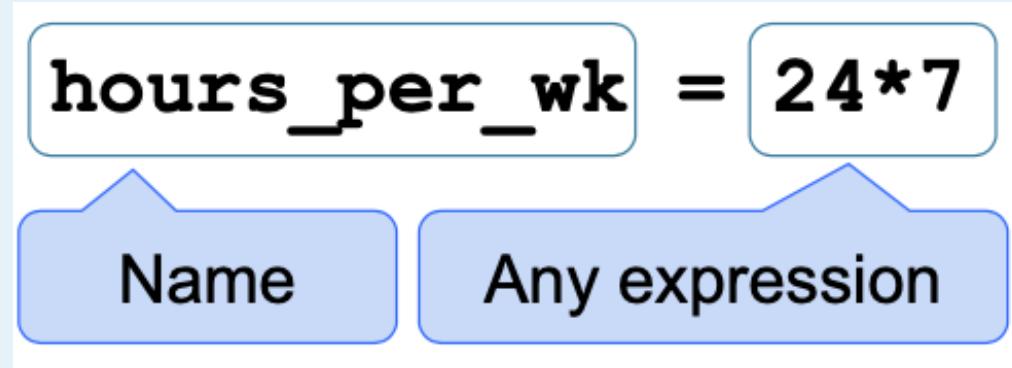

- Popular for data science & software development
- Mature data science and computational text analysis tools
- Learn through practice and doing
- Follow along in the demos

Names & Variables

Assignment Statements

- Statements perform an action
 - don't have a value
- Assignment statement changes the meaning of the name to the left of the = symbol
- The name is bound to a value (not an equation)

— Numbers —

Numbers – Integers and Floats

Two real number types in Python

- `int`: an integer of any size
- `float`: a number with an optional fractional part

An `int` never has a decimal point; a `float` does

A `float` might be printed using scientific notation

Limitations on float values

- Floats have limited size (the limit is huge)
- Floats have limited precision of 15-16 decimal places
- After arithmetic, the final few decimal places can be wrong

Strings

A string value is a snippet of text of any length

- 'a'
- 'word'
- "there can be 2 sentences. Here's the second!"

Strings consisting of numbers can be converted to numbers

- `int('12')`, `float ('1.2')`

Any value can be converted to a string

- `str(5)` becomes "5"

Discussion Question

Assume you have run the following statements:

`x = 3`

`y = '4'`

`z = '5.6'`

What is the source of the error in each example?

- A. `x + y`
- B. `x + int(y + z)`
- C. `str(x) + int(y)`
- D. `y + float(z)`

Types – Every value has a type

We've seen 5 types so far:

- int: 2
- float: 2.2
- str: 'Red fish, blue fish'

Types – Every value has a type

The type function tells you the type of a value

- `type(2)`
- `type(2+2)`

An expression's “type” is based on its value

- `x = 2, y="hello"`
- `type(x), type(y) = ???`

Strings that contain numbers can be converted to numbers

- `int("12")`
- `float("1.2")`
- ~~`float("one point two")`~~ # Not a good idea

Conversions

Any value can be converted to a string

- `str(6)`

Numbers can be converted to other numeric types

- `float(1)`
- `int(2.3)`. # DANGER: why is this a bad idea

Collections

Collections considered

Ordered:

- Lists
- Tuples

Unordered:

- Sets
- Dictionaries

- store multiple items in a single variable
 - fruit = ["bananas", "apples", "oranges"]
- Order is preserved
- Access items with brackets
 - first_fruit = fruit[0]
 - second_fruit[= fruit[1]
 - last_fruit = fruit[-1]
- What are the values assigned to these three names?

Lists – accessing sub-lists

```
fruit = ["bananas", "apples", "oranges"]
```

- Access multiple items:

- sub_fruit1 = [0:2]

- sub_fruit1 = ???

- sub_fruit2 = [:2]

- sub_fruit2 = ???

- sub_fruit3 = [0:]

- sub_fruit3 = ???

Lists – adding to lists

```
fruit = ["bananas", "apples", "oranges"]
```

- Adding at the end:
 - fruit.append("grapefruit")

- Modifying at a specific location:
 - fruit[1] = "strawberry"
 - fruit ???

Tuples

- Immutable lists
- play = ("Shakespeare", "A Midsummer Night's Dream", 1595)
- Used to group together related data

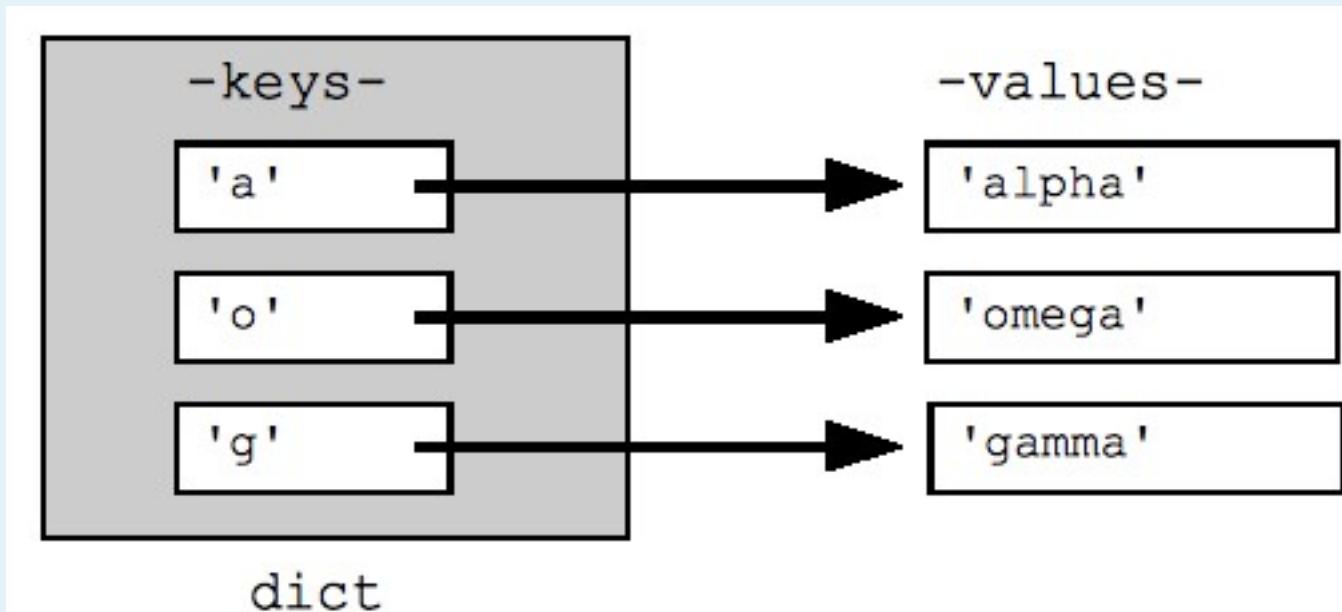

- Unordered and unindexed collection
- authors = set(["Shakespeare", "Austin", "Morrison", "Woolf"])
- No duplicates

Dictionary

- Store data values in *key:value* pairs.
- Ordered, changeable, no duplicates

- `{"a": 1,
"b": 2,
"c": 3}`

Functions

Anatomy of a Call Expression

What
function
to call

Argument to the
function

A diagram illustrating a call expression. It consists of a function name 'f' followed by a left parenthesis '(', then a parameter '27', and finally a right parenthesis ')'. All four characters ('f', '(', '27', ')') are enclosed within a dashed blue rectangular box, representing the components of the call expression.

"Call f on 27."

Anatomy of a Call Expression

What
function
to call

First argument

Second
argument

```
max(15, 27)
```

Python Built-in Functions

| Built-in Functions | | | | |
|----------------------------|--------------------------|---------------------------|---------------------------|-----------------------------|
| <code>abs()</code> | <code>delattr()</code> | <code>hash()</code> | <code>memoryview()</code> | <code>set()</code> |
| <code>all()</code> | <code>dict()</code> | <code>help()</code> | <code>min()</code> | <code>setattr()</code> |
| <code>any()</code> | <code>dir()</code> | <code>hex()</code> | <code>next()</code> | <code>slice()</code> |
| <code>ascii()</code> | <code>divmod()</code> | <code>id()</code> | <code>object()</code> | <code>sorted()</code> |
| <code>bin()</code> | <code>enumerate()</code> | <code>input()</code> | <code>oct()</code> | <code>staticmethod()</code> |
| <code>bool()</code> | <code>eval()</code> | <code>int()</code> | <code>open()</code> | <code>str()</code> |
| <code>breakpoint()</code> | <code>exec()</code> | <code>isinstance()</code> | <code>ord()</code> | <code>sum()</code> |
| <code>bytearray()</code> | <code>filter()</code> | <code>issubclass()</code> | <code>pow()</code> | <code>super()</code> |
| <code>bytes()</code> | <code>float()</code> | <code>iter()</code> | <code>print()</code> | <code>tuple()</code> |
| <code>callable()</code> | <code>format()</code> | <code>len()</code> | <code>property()</code> | <code>type()</code> |
| <code>chr()</code> | <code>frozenset()</code> | <code>list()</code> | <code>range()</code> | <code>vars()</code> |
| <code>classmethod()</code> | <code>getattr()</code> | <code>locals()</code> | <code>repr()</code> | <code>zip()</code> |
| <code>compile()</code> | <code>globals()</code> | <code>map()</code> | <code>reversed()</code> | <code>__import__()</code> |
| <code>complex()</code> | <code>hasattr()</code> | <code>max()</code> | <code>round()</code> | |

Control Statements

Loops

Say we have a list of author names, how can we find the length of each name?

Conditionals

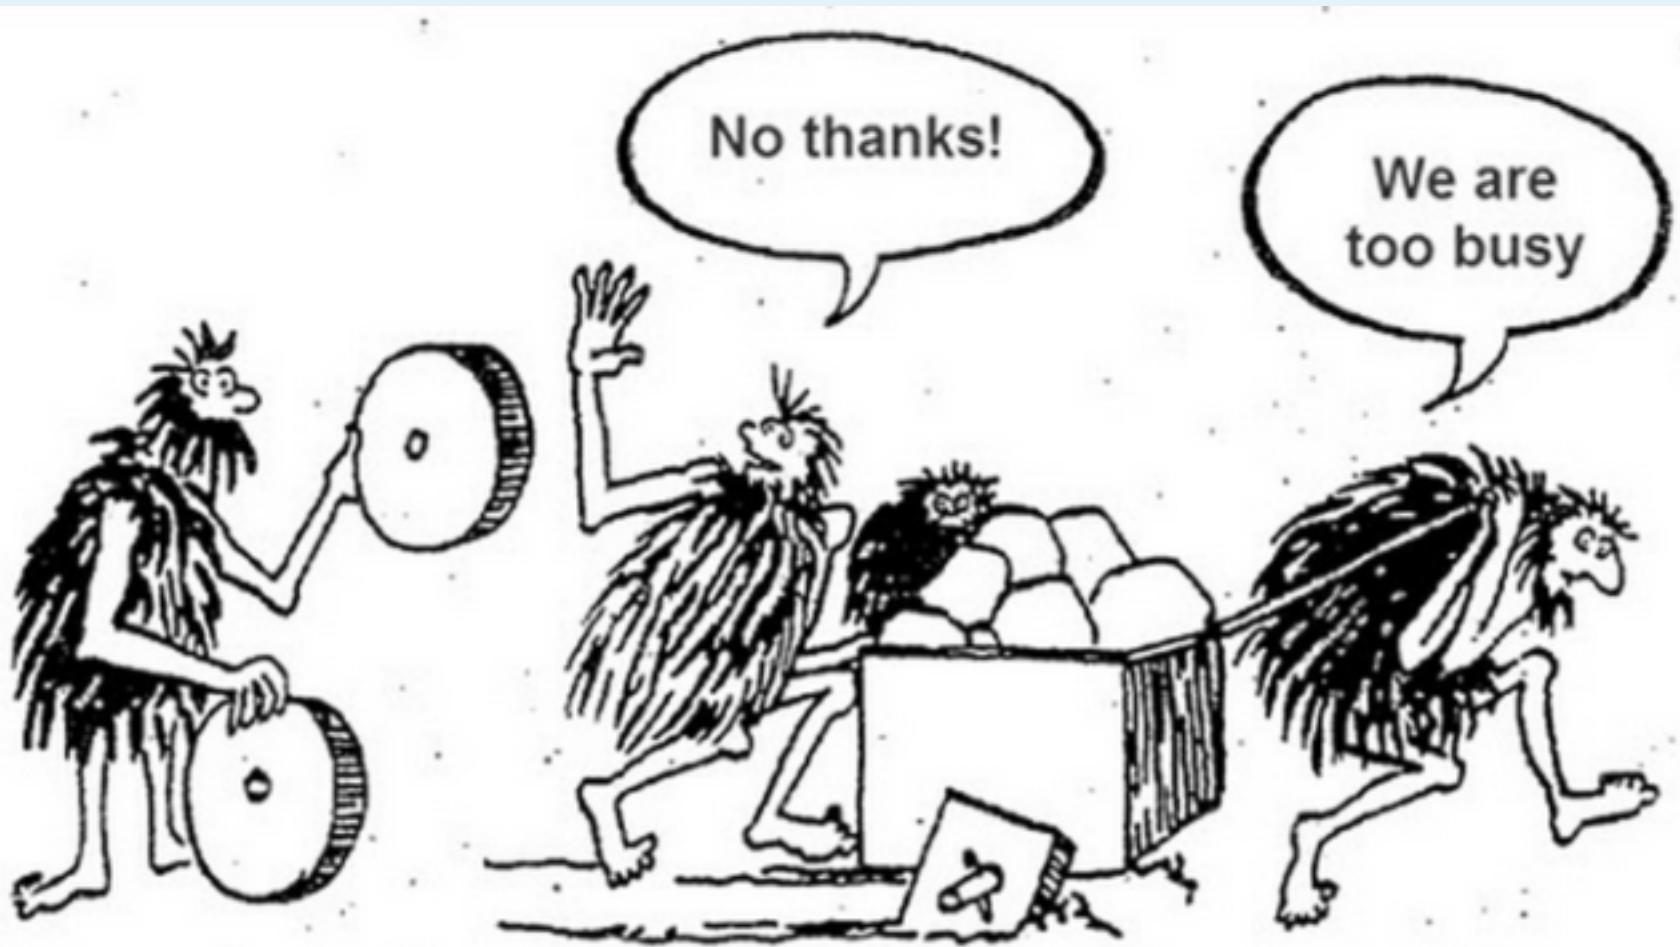

Only apply computation under certain scenario

BARNARD

Libraries

- Don't reinvent the wheel

Installing and Accessing Python Libraries

- Install via command line:
 - pip install <Library Name>
- Access library in python:
 - import <Library Name>

Libraries we will use

- BeautifulSoup – webscraping
- Nltk – Processing text
- Spacy - Processing text
- little_mallet – Topic Modeling
- Pandas - Tables
- Matplotlib - Visualization
- Numpy – Vectors
- Sklearn – Machine Learning
